## ACKNOWLEDGEMENTS

## Formal acknowledgement of academic support

I am extremely grateful for the support I have received from both of my supervisors at the London School of Hygiene and Tropical Medicine.

## Project development

Dr Edwards and Dr Morgan had the initial idea to analyse cycling injuries by gender. I developed this idea and decided to analyse female rates of cycling and injury in UK cities. My supervisors continued to help me formulate this project through regular discussion. I then devised the study design and decided on data sources used for analysis. I also decided to undertake an extensive literature review on this subject in order to explore the wider subject of female cycling.

## Contact, input and support

Both my supervisors met me together, fortnightly, during the first six weeks of the project period to offer overarching guidance on the direction of my project and analysis of data. I also had another meeting with Dr Morgan, during the later phase of the project period, to discuss preliminary results and analysis. Both supervisors commented on the first draft of my project, offering minor suggestions for improvement, and continued to support me by email during the final weeks of the project period.

## Main research work

I conducted the literature review and the collection, extraction and analysis of data for this project myself. I was given advice on STATS19 data by my supervisors and was able to discuss analysis techniques with them.

## Acknowledgement of other support

I am grateful to Dr Rebecca Steinbach who also kindly assisted me in understanding how to merge STATS19 datasets at the beginning of my project.
I also acknowledge the help I received from the National Travel Survey and, in particular, Glenn Goodman, who has generously taken time to help with the provision of data for this project. Similarly, personal correspondence with Carole Austin, from the 'Census Helpdesk' has been helpful in informing my knowledge in this area.

## ABBREVIATIONS AND NOTES

| CI | Confidence Interval |

| Yr | United Kingdom |

Results in this project are given to the nearest whole number for population and numbers of cyclists, one decimal place for percentages, rates and ratios, two decimal places for confidence intervals (CI) and three decimal places for probabilities, unless otherwise stated.

#### Abstract

\section*{Background}

Recognition of the health, environmental and economic benefits of 'active travel', has led to calls to increase cycling uptake. Whilst these benefits are known to extend to women, there have historically been few female commuter cyclists in the United Kingdom (UK). There is also concern that females are at more risk of being killed or seriously injured (KSI) than males, potentially further discouraging women from cycling. This project investigated female cycling uptake and cyclist KSI rates in ten UK cities.

## Methods

This research used STATS19, Census, Office for National Statistics and National Travel Survey data to analyse cycling uptake and KSI rates, from 2005-2013. Working age cyclists in London, Birmingham, Bradford, Bristol, Cardiff, Leeds, Leicester, Liverpool, Manchester and Sheffield were included. Rates were calculated using exposure measures of population, number of people who cycle to work and total miles cycled.

## Results

Barriers to female cycling include environmental and safety concerns and conflicts with female identity and responsibilities. Cycling uptake remains low in England and Wales, with $1.6 \%$ of women cycling to work, though this varies geographically. On average, $21.8 \%$ of London KSI cyclists are female; nationally, numbers of women KSI vary but are highest in London and Bristol. Female rates also vary geographically; comparing female with male cyclists, KSI relative risk decreased by $7 \%(\mathrm{Cl} 0.87-1.01$; $\mathrm{p}=0.078$ ), but this altered depending on exposure measure used.

## Conclusions

Cycling remains 'gendered' in the UK, with fewer women cycling compared with men and with other countries. Public health bodies need to reduce geographical variation in cycling uptake and KSI rates. The female to male KSI rate ratio also varies depending on exposure measured used. Population-based exposure measures are particularly flawed for assessing cycling risk by gender and there is need for international agreement on the most accurate measure to use.
(Word count: 298)

## 1. INTRODUCTION

Cycling is a form of 'active travel', which has been suggested as a method of preventing and treating long term health conditions, such as the huge burden of disease from obesity (1). It is seen as a key way to facilitate this because it is thought to improve health in multiple ways (2)(3)(4), and because the health benefits from cycling outweigh the risks from it (5)(6). Evidence suggests that the benefits from commuter cycling may also be particularly relevant to women as they are otherwise less likely than men to incorporate regular exercise into their daily routine (7). Increased 'active travel' may also produce financial benefits, with an estimated saving to the National Health Service (NHS) of $£ 17$ billion (8). Alongside these health and economic benefits, increasing cycling uptake is also recognised as a potential way of reducing the environmental damage from other forms of transport (9)(10) and, together, these arguments have led to a public health drive to encourage cycling (11)(12)(13).

Yet, despite this increased policy drive and political will, uptake of cycling across the United Kingdom (UK) has historically been varied. Evidence suggests that there has been a general increase in pedal cycle traffic in the UK (14), particularly in cities such as London, where the number of cyclists using the Transport for London Road Network has grown by '173\% between 2000/01 and 2011/12' (15). However numbers cycling are much lower in other parts of the UK and 'rare' in some cities (16), and women have previously cycled less than their male counterparts throughout the UK (16). There is also persistent concern regarding the number of killed or seriously injured cyclists (KSI). In London, KSI cyclists 'were up 16\%' in 2013 (15) and have also increased nationally, with numbers 11\% higher in 2008 than 2004 (17) and cyclists representing the sole road user type in whom numbers have not decreased (14). However, previous research has also suggested that this increase may not be uniform, with wide geographical variation in KSI numbers (17). Of perhaps even greater concern, media reports have described a potential gender difference in the number of cyclists KSI, with headlines such as 'Are women cyclists in more danger than men?' (18) and 'Women cyclists are more likely to be killed in traffic: TfL suppresses report' (19), fuelling perception of an increased risk to female cyclists (20).

However, clarifying these statistics remains problematic because of difficulties in recording collisions and in reliably measuring cyclists' exposure to injury (21). The latter is particularly controversial because use of different exposure methods can affect rates of injury. Indeed the 'Road Danger Reduction Forum' recently called Transport for London's (TfL) use of overall population numbers as an exposure measure for cycling, 'disgraceful' (22). Together,
these methodological, geographical and temporal variations mean that it is currently unclear if females actually do represent a larger proportion of the total number of cyclists KSI in UK cities. Yet the question of whether this risk is real or perceived is important because it is likely that this concern is affecting some women's desire to use cycling for daily commuting and because any actual difference might offer the potential for targeted road safety campaigns.

## 2. AIMS AND OBJECTIVES

### 2.1 Aims

This project aims to investigate female cycling in London and other UK cities over the last decade. I aim to review the literature to explore the reasons for historical differences in female and male cycling uptake, before comparing the number of males and females now using cycling as a form of transport in the UK. I will then analyse the number of male and female cyclists KSI and the rates of cyclists KSI by exposure, between 2005 and 2013. I aim to compare London results with the results of nine other UK cities (Birmingham, Bradford, Bristol, Cardiff, Leeds, Leicester, Liverpool, Manchester and Sheffield) to gain an understanding of whether any changes seen are reflected nationally, before discussing these results in the context of the wider literature.

### 2.2 Objectives

1. To undertake a brief critical review of the literature into:
a. Gender differences in cycling uptake
b. Motivators and barriers to female cycling for transport
c. Gender differences in risk of injury
2. To compare the numbers of males and females using cycling as a method of transport to work in London and nine other UK cities
3. To compare the numbers of male and female cyclists KSI in ten UK cities, between 2005 and 2013
4. To compare the unadjusted rates of male and female cyclists KSI in ten UK cities, between 2005 and 2013
5. To compare the adjusted rates of male and female cyclists KSI in ten UK cities, between 2005 and 2013

## 3. CRITICAL REVIEW OF THE BACKGROUND LITERATURE

### 3.1 Gender differences in cycling uptake

There is a growing body of evidence supporting the existence of differences in cycling behaviour between men and women (7). This demonstrates a difference between 'carorientated cities with low levels of cycling', where most cyclists are young or middle-aged males, and 'cycling-friendly cities', where women are much more likely to cycle (7). Previous research suggests that London, and the UK as a whole, has been part of the former category: nationally, men make about twice as many trips annually (23) and travel four times further than females by bicycle (24), with ' $72 \%$ of cycle journeys being made by men in 2012/13' in London (15). Evidence from London's Cycle Hire Scheme supports this, with the findings that women made less than a fifth of all trips (25) and that their usage was lighter and dominated by leisure-orientated journeys (26). This is also in keeping with research from other countries such as Canada (27), the USA (28) and Australia (29), where women make up around $25 \%$ of all commuter cyclists (30).

However not all countries follow this pattern and in countries such as the Netherlands and Denmark female cyclists constitute up to $55 \%$ of all cyclists (31). Research also suggests that countries with low rates of utilitarian cycling have substantial gender differences in cycling, whilst those with cycling as a higher overall modal share have a smaller, or even no, gender difference (7). This variation may also be seen in cyclists' ages, with a greater agerelated reduction in female cycling seen in countries with overall low rates of women cycling (7).

### 3.2 Motivators and barriers to female commuter cycling

Motivators and barriers to cycling are inherently personal and the literature suggests they may depend on both 'life stage' and 'circumstances' (32). For women, they are varied and can include 'intrapersonal, interpersonal, institutional, community, and environmental factors' (33). Evidence suggests that many motivators are similar for male and female cyclists and include enjoyment (34) and those 'related to health' and 'fitness' (30). Yet other motivators, such as those related to costs, convenience and the environment, may be more important to women than men (30). Cycling also provides more 'autonomy' and 'efficiency' to female cyclists than other forms of transport (35) and its association with a 'bourgeois sensibility' of environmental and personal health may further increase female cycling motivation (35).

However the literature suggests that the differences in barriers to cycling may be even more starkly 'gendered' than motivators are. Whilst much of the research into the effect of gender on cycling behaviour comes from observational studies, several main themes emerge from the literature, including: how cycling fits into women's responsibilities, cycling in relation to sense of self and femininity, and traffic and environmental safety concerns.

Several studies have explored the negative relationship between cycling and female responsibilities (34), such as the need to carry goods and passengers (34). Activities such as shopping, working and picking up children can constrain women's ability to engage in regular cycling (33). The more complicated nature of these journeys, such as the requirement to 'trip-chain' (7), may still further increase this barrier. Yet these constraints do not seem universal and appear to be reduced in countries such as the Netherlands, where women cycle as often as men and shopping trips by bicycle make up a higher proportion of total trips (31).

The idea that most cyclists are male, white and from affluent social groups (35) may be an inherent part of another barrier to female cycling: the difference between female cyclists' sense of self and the identity that 'being a cyclist' brings (35). This barrier encompasses practical aspects such as difficulties with hair, make-up and weather protection (35)(33). However it also involves more intangible ones such as feelings of 'impropriety' (35), embarrassment and the incongruity of the risk and aggression of cycling with the female sense of self (35). This barrier appears further exaggerated for women from 'Black and Asian' backgrounds (35) who may feel cycling is 'inappropriate' and 'irrelevant' because it requires exposure of their bodies, unsuitable clothing, is culturally alien and even associated with poverty (35). Research suggests that practical support, such as showers, lockers, and dress codes at work, and social influences can have a positive effect on women's engagement with cycling (33).

However the literature suggests that perhaps the greatest barrier to cycling for women is their concern about traffic and environmental safety (29), with women citing a 'greater concern for safety while cycling than men' (27). Survey evidence from Australia suggests that female cyclists are significantly more likely than men to report traffic and other motorists' aggression as constraints (30) and similar findings are reported by American (34), Canadian (27) and British studies (35). This may be because women are more risk averse than men (29) and, together, these barriers may lead to behaviour change, with research suggesting that female cyclists may be more influenced by road type than males (34), preferring to cycle on off-road paths (29). Nevertheless, overcoming these barriers, for example through
improved infrastructure, may also offer an opportunity to increase female cycling, as evidence suggests that bike-friendly environments encourage female cycling (33).

### 3.3 Gender differences in risk of injury

There is much debate about whether female cyclists' perceptions of cycling risk are justified or are based on 'psychological, cultural and social factors' (7). Analysis of cyclist deaths in London between 1985 and 1992 showed that around $70 \%$ were male (36) and, between 1992 and 2006, approximately a quarter were found to be female, with more female deaths in Inner London than Outer (37). More recent Transport for London (TfL) data has supported this and shown that males 'accounted for $77 \%$ of pedal cyclists casualties in 2012/13' with an average $72 \%$ of cycle journeys...made by men in 2012/13' (15). Previous research, looking at data for the whole of Great Britain, supports that most cyclist casualties are male even when allowing for greater exposure (17). However other evidence found geographical variation in the proportion of males and females injured, noting that, between 2001 and 2006, females made up $26 \%$ of fatalities in London but only $19 \%$ in Great Britain (38). Other evidence also states that there is no gender difference in cycling casualty risk when exposure is taken into account (24).

Thus the extent of any gender difference in KSI risk remains unclear, as does what might underlie any potential difference. Evidence suggests that, as in other studied areas of risktaking behaviour, men are more likely to take risks in cycling related tasks than women (39), which may explain an increased KSI risk. However others contend that this risk aversion may in fact put female cyclists at increased risk of particular kinds of collisions, such as those when a heavy-goods vehicle (HGV) turns left into a cyclist (40), collisions which are often fatal. This may be because women misjudge the level of risk of overtaking HGVs on the right, preferring to stay on their left hand side and thereby actually increasing the risk of injury (40); this argument has fuelled public and media concern that female cyclists may be more at risk than males.

## 4. MATERIALS AND METHODS

### 4.1 Data inclusion and exclusion

In this project I have investigated the number of males and females cycling in ten UK cities for commuting purposes. Although it was not possible to know which cyclists were commuting, restricting cyclists to those of 'working age' only, offered at least a proxy measure for this and also reflects a main target group that policy aims to target to increase 'active travel'. Thus, after analysing data for all ages, subsequent analysis was for cyclists of working ages only, with all calculations performed for both male and female cyclists, to allow gender comparison.

I have analysed data from 2005 until 2013, in order to overlap with and update previous cycling reports that have reviewed data until the mid-2000s (37)(38)(17), and to include the most up-to-date data available (2014 data unpublished).

I included 33 London boroughs ${ }^{1}$ and nine comparison cities for analysis, with results for 'Greater', 'Inner' and 'Outer London' calculated from the results of their constituent Boroughs. City comparisons were made with Birmingham, Bradford, Bristol, Cardiff, Leeds, Leicester, Liverpool, Manchester and Sheffield; these were chosen because they are the ten most densely populated District Local Authorities (DLAs) that can be clearly identified as an individual city in Census data ${ }^{2}$. DLAs referring to outer areas of cities, e.g. Greater Manchester, were excluded, thereby allowing this project to make direct city comparisons and because these DLAs are most likely to be affected by the policies of the city's main council alone. For analysis of city data, I primarily compared these nine cities with Inner London (i.e. ten cities) as I felt that this was most comparable to other inner city DLAs; Greater London and Outer London totals are given for information.

[^0]
### 4.2 Sources of data

I obtained data for this project from several sources. Collision statistics were extracted from STATS $19^{3}$ (2005-2013), a data set of all accidents involving personal injury on public roads, which have been recorded by police officers. Data for cycling exposure, by DLA, were available from several sources: population estimates from Office for National Statistics (ONS) mid-year population estimates ${ }^{4}$ (2005-2013) and the number (no.) of persons travelling to work by bicycle, from Census data ${ }^{5}$ (2001 and 2011). Data on the average distance cycled by adults by gender per year per region (until 2012), were available from the National Travel Survey (NTS) ${ }^{6}$, 'household survey' that collects information on personal travel patterns in Great Britain' (41).

### 4.3 Data analysis methods

## 4.3.i Numbers of cyclists

I estimated yearly totals for 'number of persons travelling to work by bicycle' by dividing the total increase between 2001 and 2011 (Census data) by ten, to derive a yearly increase; this was then added to 2001 (for years 2005-2010) and 2011 data (for years 2012-13). The 2011 Census combines City of London data with Westminster data, thus this analysis also combined KSI STATS19 data for these two Boroughs, from 2011 onwards, to allow direct comparisons.

## 4.3.ii Numbers of cyclists KSI

I downloaded STATS19 data and merged police 'Accident' and 'Casualty' files. Data were then restricted to collisions involving a pedal cyclist as the casualty (Variable: Casualty Type; Code $1^{7}$ ), before further analysing the age and gender of KSI cyclists, by DLA. From this data, I calculated total numbers, means, standard deviations (SDs), standard errors (SEs) and confidence intervals (CI) for KSI cyclists and totals and means were used as a numerator for calculations of KSI rates.

[^1]
## 4.3.iii KSI rate

In order to calculate rates of KSI cyclists, I used three different measures of cyclist exposure:

1) the total population of males/females in the DLA; 2) the number of people cycling to work;

3 ) the total miles cycled. I then calculated rates using the general formula:

Rate $=\quad \quad$ Number (no.) of events (KSI cyclists)
Exposure: (1) total population / 2) no. of people cycling to work / 3) total distance cycled

I used these three measures because there is no single, uniformly recognised, exposure data set or method available and they therefore offered three alternative ways of calculating exposure. They also offered this project the potential to conclude that any results found are valid, regardless of exposure method used.

I calculated each of the three exposure measures, as follows:

1) I extracted population data from ONS sources (see above).
2) I extracted and estimated annual totals of no. people who cycle to work from Census data (see above).
3) As NTS data on average miles cycled per cyclist per year is only available at regional level, I extracted and used data for the region that included each city e.g. North West region data for both Liverpool and Manchester. Data is also unavailable for 2013, because changes to survey methods mean that these results are not comparable to previous years, thus I estimated average miles for 2013 by adding the average change over the previous 7 years to 2012 data. Total miles cycled were then calculated for all years and cities in two ways: 1) average male/female miles multiplied by the total male/female population for that DLA and year; 2) average male/female miles multiplied by the total males/females travelling to work by bicycle, for that DLA and year.

Thus, in total, I analysed KSI rates using four different exposure measures.

## 4.3.iv Statistical testing

The Wald test, assuming the Poisson distribution, was used to test the relationship between the rate of being KSI and gender, to account for possible confounding in this relationship; this was repeated using each of the four exposure measures, to allow comparison of results.

The skewed shape of the Poisson Distribution makes it appropriate for analysis of small means (42) as was the case in this data.

I analysed all data in this project using STATA13 (STATACorp, USA) and Microsoft Excel 2011 (Microsoft Corporation, USA).

### 4.4 Literature search

I performed a background literature search using the terms:

- Gender: "female", " women", "woman", "sex"
- Bicycle: "cycle", "cycling", "cyclist", "bicycling", "bicyclist", "bike", "biking", (with the terms "ovarian", "hormone", "cell" and "elite" excluded),

I searched for English language publications from 2000-2014 in: Web of Science, PubMed, the Cochrane Database of Reviews and TRID (Transport Research International Documentation) database, and performed snowball searches where relevant. I also searched some of the grey literature on cycling, including websites from CTC (the National Cycling Charity), Sustrans, the Department of Transport, Transport for London and the search engine 'Google'.

### 4.5 Ethical considerations

The Research and Ethics Committee of the London School of Hygiene and Tropical Medicine granted ethical approval for this research. None of the data in this research allow identification of individuals.

## 5. RESULTS

### 5.1 Comparison of the numbers of males and females using cycling as method of transport to work in London and nine other UK cities

For males and females, the proportion of people who travelled to work by bicycle in England and Wales remained similar between 2001 and 2011. In 2001, 3.7\% of males who travelled to work, over the age of 16 , used a bicycle ( $4.1 \%$ when excluding home workers ${ }^{8}$ ) (appendix 1); by 2011, this figure had very slightly increased to $3.9 \%$ ( $4.4 \%$ when excluding home workers). In comparison, in 2001, $1.6 \%$ of all females used a bicycle ( $1.8 \%$ excluding home workers), which remained the same in 2011. In 2011, of all workers who recorded their method of travel to work as cycling, $73.2 \%$ were males and $26.8 \%$ were females, unchanged from 2001, a ratio of 2.7:1.

Table 1: Percentage (\%) of males/females cycling to work (as a percentage of total males/females of all ages) in ten city comparisons and Inner and Outer London

| City | Percentage of total respondents, by year of Census and gender (M/F) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Liverpool | 2.9 | 3.3 | 0.3 | 0.5 | 0.7 | 0.2 |
| Manchester | 4.7 | 5.4 | 0.8 | 1.6 | 2.2 | 0.6 |
| Sheffield | 1.7 | 2.7 | 1.0 | 0.3 | 0.7 | 0.4 |

There has been a varied change in the level of cycling to work across the UK (table 1). There has been a notable increase in the proportion of both male and female cyclists in London and Bristol, with the increase in Greater London predominantly due to the increase

[^2]in Inner rather than Outer London. In 2011, for both men and women, Bristol has the highest percentage of people commuting to work by bicycle, with $10.0 \%$ of men and $4.6 \%$ of women; Inner London has the next highest totals for both, with $8.6 \%$ of men and $4.5 \%$ of women.

Leicester had the greatest difference in percentage cyclists over the decade despite having relatively high proportions cycling for both genders in 2001. Bradford had the lowest percentage of people commuting by bicycle for males and females, in both 2001 and 2011.

### 5.2 Comparison of the numbers of male and female cyclists KSI in London and nine other UK cities, between 2005 and 2013

## 5.2.i KSI cyclists in London

There have been 45 female and 92 male cyclists killed in Greater London between 2005 and 2013 (table 2) (per year, males: mean 10.2, SD 4.2; females: mean 5.0, SD 2.7). Across all years and injury severities, there are more males injured than females, other than for female 'fatal' injuries in 2009. There has been an overall increase in the number of cyclists KSI between 2005 and 2013 (per year, males: mean 374.2, SD 75.9; females: mean 103.7, SD 18.6) (figure 1). For both, the number increased steadily between 2009 and 2012, when it peaked, and then reduced again in 2013.

Table 2: Numbers of injured cyclists (of all ages) in Greater London by year, gender and injury severity

| Year | Severity of Injury and no. of cyclists by gender (M/F) |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Slight (no.) |  | KSI |  |  |  |  |  |  |  |
|  |  |  | Serious (no.) |  | Fatal (no.) |  | Total KSI (no.) |  |  | F as \% of total KSI for year |
|  | M | F | M | F | M | F | M | F | All |  |
| 2005 | 1977 | 546 | 283 | 68 | 18 | 3 | 301 | 71 | 372 | 19.1 |
| 2006 | 2010 | 556 | 282 | 91 | 11 | 8 | 293 | 99 | 392 | 25.3 |
| 2007 | 1953 | 556 | 353 | 93 | 11 | 4 | 364 | 97 | 461 | 21.0 |
| 2008 | 2128 | 629 | 338 | 92 | 11 | 4 | 349 | 96 | 445 | 21.6 |
| 2009 | 2502 | 734 | 337 | 83 | 3 | 10 | 340 | 93 | 433 | 21.5 |
| 2010 | 2756 | 784 | 358 | 99 | 6 | 4 | 364 | 103 | 467 | 22.1 |
| 2011 | 2974 | 952 | 437 | 118 | 10 | 6 | 447 | 124 | 571 | 21.7 |
| 2012 | 3078 | 864 | 525 | 132 | 13 | 1 | 538 | 133 | 671 | 19.8 |
| 2013 | 3197 | 937 | 363 | 112 | 9 | 5 | 372 | 117 | 489 | 23.9 |
| TOTAL | 22575 | 6558 | 3276 | 888 | 92 | 45 | 3368 | 933 | 4301 |  |

The ratio of total males to females for the three categories was: fatal 2.0:1, serious 3.7:1, slight 3.4:1, suggesting that a higher proportion of 'fatal' collisions involved female cyclists. The percentage of KSI cyclists who are female has also varied ((range: 19.1\% (2005) $25.3 \%$ (2006); mean $21.8 \%$; SD 1.9). Whilst there appears to have been a slight increase in the proportion that are female in $2013(23.9 \%)$ there has been no consistent pattern to suggest a change in this.

Figure 1: Total numbers of KSI cyclists (of all ages) in Greater London, by year

Analysis of age bands of cyclists demonstrated that, over the nine years, $90.0 \%$ of females and $85.7 \%$ of males KSI in London were between the ages of $16-65$ years (appendix 2, figure 2).

As previously explained, because of the aims of this project to focus on working age cyclists, all results from this point forward refer to those cyclists between 16-64/65 years ${ }^{9}$, unless otherwise stated.

[^3]Figure 2: Annual total numbers of KSI cyclists (of all ages) in Greater London, between 2005-2013 (all years combined)

For Greater London, the mean number of KSI cyclists was 320.8 (CI 262.0-379.6) for men and 93.3 (CI 8.3-108.4) for women. When comparing Inner London and Outer London, the number of cyclists of working age KSI is greater in Inner London across all years and for both genders (appendix 3, figure 3). However, in all years apart from 2006, Inner London females constituted a bigger percentage of Greater London female totals, than Inner London male percentages did and the increase in Inner London female cyclists KSI has been greater over the nine years than in Outer London.

There is wide variation in numbers of working age cyclists KSI across the London Boroughs (appendix 4, figure 4). For both genders, in Outer London, the greatest totals were in Richmond upon Thames; in Inner London, Westminster and Lambeth were highest. For Inner and Outer London, Boroughs with the highest numbers of KSI cyclists for one gender tended to also be the highest for the other gender.

Figure 3: Yearly total numbers of KSI cyclists (of working age) in Inner and Outer London, from 2005-2013, by gender and year
$\longrightarrow$ Males Outer London $\quad$ Males Inner London
$\bullet \bullet$ Females Outer London $\quad$ Females Inner London

Figure 4: Total numbers of KSI cyclists (of working age) by London Borough (all years combined), by gender

## 5.2.ii KSI in comparison cities

As in London, the vast majority of KSI cyclists for the nine other cities were between 16-65 years ( $84.7 \%$ females; $80.4 \%$ males (appendix 5 )), adding weight to my decision to analyse working age cyclists only.

The greatest total number of KSI cyclists (of working age) was in Inner London (appendix 6, figure 5); this dwarfed the numbers in the other comparison cities. When looking at females alone, Inner London has approximately twelve times the total number (646) of females KSI than the next highest city, Bristol (54).

Figure 5: Total numbers of KSI cyclists (of working age) in ten city comparisons (all years combined)

When KSI cyclists for the nine cities are compared, with London removed (figure 6), Bristol had the highest number of women, followed by Manchester and Leeds; Leicester, Bradford and Cardiff had the lowest numbers. There are no trends apparent in the numbers of KSI female cyclists other than the general increase seen in Inner London. The lowest total proportion of males to females KSI was seen in Inner London (3.0:1) and Bristol (3.6:1) although there was considerable variation from year to year and geographically, with the highest ratio of 14.7: 1 seen in Leicester (appendix 7).

Figure 6: Total numbers of KSI cyclists (of working age) in nine city comparisons, excluding London (all years combined)

When comparing the mean number of female cyclists KSI over the nine years (appendix 8), Inner London (mean $=71.8$ ) had more than Bristol, the next highest (mean $=6.0$ ). The average numbers for all other cities were much lower, with Leicester the lowest (mean = 0.7 ). For men (appendix 9), Inner London also had the highest mean (217.9), with Leeds the next highest (28.3) and Cardiff the lowest (8.3).

### 5.3 Comparison of the unadjusted rate of male and female cyclists KSI in ten UK cities, between 2005 and 2013

## 5.3.i Using population estimates as an exposure measure

I calculated rates (numbers of male/female cyclists KSI per 100000 men/women) (table 3, appendix 12) using mid-year population estimates (appendices 10, 11) and KSI numbers (appendix 6).

Table 3: Rates of male/female cyclists KSI per 100000 men/women ${ }^{10}$

| City/area | Rate, year and gender (M/F) |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{2 0 0 5}$ |  | $\mathbf{2 0 1 2}$ |  | 2013 |  | All years average |  |
|  | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) |
| Outer London | 5.2 | 0.9 | 8.4 | 1.6 | 5.9 | 1.1 | 6.1 | 1.3 |
| Inner London | 17.3 | 4.7 | 31.3 | 8.8 | 19.8 | 8.3 | 21.0 | 6.9 |
| Greater London | 9.8 | 2.4 | 17.1 | 4.3 | 11.2 | 3.8 | 11.7 | 3.4 |
| Birmingham | 4.4 | 0.3 | 10.4 | 0.9 | 7.5 | 1.4 | 7.3 | 0.6 |
| Bradford | 8.4 | 0.6 | 7.9 | 2.4 | 12.2 | 0.6 | 7.5 | 0.8 |
| Bristol | 11.4 | 5.1 | 16.7 | 2.1 | 9.3 | 2.7 | 14.7 | 4.2 |
| Cardiff | 7.4 | 0.9 | 7.6 | 0.0 | 6.7 | 1.7 | 7.3 | 1.2 |
| Leeds | 7.4 | 0.4 | 15.6 | 1.6 | 16.4 | 1.2 | 11.4 | 1.5 |
| Leicester | 2.0 | 1.0 | 13.5 | 0.0 | 12.5 | 0.0 | 9.0 | 0.6 |
| Liverpool | 7.3 | 2.0 | 16.0 | 1.2 | 19.1 | 2.5 | 10.7 | 1.4 |
| Manchester | 9.3 | 3.2 | 15.1 | 2.8 | 10.7 | 4.0 | 12.0 | 2.4 |
| Sheffield | 9.8 | 1.2 | 9.2 | 1.1 | 9.2 | 2.2 | 9.8 | 1.1 |

Inner London had the highest rate of KSI cyclists per female population in 2013 and had the highest average KSI rate over the nine years. When looking at the average female rate, Bristol was second highest behind Inner London. Whilst Inner London also had the highest rate of KSI for males, other cities did not follow the same pattern as female rates and Liverpool and Leeds also had high 2013 male rates. However, when looking at the average rate for males, Inner London and Bristol were also the highest.

When comparing male and female rates, males have a higher rate of KSI cyclists than females with male rates more than 3 times higher for nearly all cities and years. For average values, Inner London females had a higher KSI ratio to men of $1: 3$, with Bristol next highest at 1:3.8.

## 5.3.ii Using number of people who travel to work by bicycle as an exposure measure

I calculated rates (numbers of male/female cyclists KSI per 1000 men/women who travel to work by bicycle) (table 4, appendix 17) using numbers of people who travel to work data (appendices 13, 14, 15 and 16) and KSI numbers (appendix 6).

[^4]Table 4: Rates of male/female cyclists KSI per 1000 males/females who cycle to work) ${ }^{11}$

| City/area | Rate, year and gender (M/F) |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2005 |  | 2012 |  | 2013 |  | All years average |  |
|  | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) |
| Outer London | 2.5 | 1.4 | 3.5 | 2.0 | 2.4 | 1.3 | 2.7 | 1.7 |
| Inner London | 3.8 | 2.2 | 4.6 | 2.8 | 2.8 | 2.5 | 3.6 | 2.5 |
| Greater London | 3.3 | 1.9 | 4.2 | 2.6 | 2.7 | 2.2 | 3.2 | 2.3 |
| Birmingham | 3.0 | 1.1 | 6.7 | 2.4 | 4.8 | 3.9 | 4.8 | 1.8 |
| Bradford | 9.4 | 5.7 | 8.7 | 19.5 | 13.2 | 4.8 | 8.3 | 6.3 |
| Bristol | 2.0 | 2.4 | 2.1 | 0.6 | 1.2 | 0.8 | 2.1 | 1.5 |
| Cardiff | 2.4 | 0.9 | 2.1 | 0.0 | 1.8 | 1.1 | 2.1 | 0.9 |
| Leeds | 4.3 | 1.3 | 7.4 | 3.5 | 7.5 | 2.5 | 5.8 | 3.8 |
| Leicester | 0.5 | 1.0 | 3.8 | 0.0 | 3.5 | 0.0 | 2.5 | 0.6 |
| Liverpool | 4.1 | 6.0 | 7.7 | 2.7 | 8.9 | 5.2 | 5.4 | 3.5 |
| Manchester | 3.3 | 3.3 | 4.3 | 2.1 | 3.0 | 2.9 | 3.7 | 2.0 |
| Sheffield | 6.6 | 3.7 | 4.7 | 2.3 | 4.6 | 4.3 | 5.7 | 2.5 |

Liverpool and Bradford had the highest rates of KSI cyclists per 1000 females cycling to work in 2013, with Sheffield and Birmingham next highest. Bradford stood out with the highest average female KSI rate over all the years. Leicester, Cardiff and Bristol had the lowest average rates for female cyclists and in 2013. A similar ranking of cities was seen for male totals and averages. Inner London was ranked amongst the middle cities for males and females in 2012, 2013 and in the average.

When comparing average KSI rates, males were higher across all cities and years. However for all cities, the ratio of average male to female rates are much closer than when using population as an exposure measure; with many lower than double, such as in Inner London and Bristol where the ratios are 1:1.4. There have also been several years where the female rate is greater than or equal to the male rate, such as in Manchester in 2005, Liverpool in 2005 and 2007, Birmingham and Leeds in 2006, Cardiff in 2008 and 2009, Bradford in 2010 and 2012 and Bristol in 2011.

[^5]
## 5.3.iii Using distance travelled by bicycle as an exposure measure

I calculated rates (numbers of male/female KSI cyclists per annual total male/female miles cycled) (table 5, appendix 20) using KSI numbers (appendix 6) and total miles cycled, calculated in two ways (see methods; appendices 18 and 19).

Table 5: Rates of male/female cyclists KSI per 1,000 000 total male/female miles cycled annually (using population for calculation)

| City/area | Rate, year and gender (M/F) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{2 0 0 5}$ |  | $\mathbf{2 0 1 2}$ |  | 2013 |  | All years average |  |  |
|  | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) |  |
| Outer London | 0.5 | 0.4 | 0.7 | 0.4 | 0.5 | 0.3 | 0.5 | 0.4 |  |
| Inner London | 1.6 | 1.8 | 2.5 | 2.2 | 1.5 | 2.0 | 1.9 | 2.0 |  |
| Greater London | 0.9 | 0.9 | 1.4 | 1.1 | 0.9 | 0.9 | 1.0 | 1.0 |  |
| Birmingham | 1.3 | 0.4 | 1.1 | 0.5 | 0.8 | 0.7 | 1.2 | 0.5 |  |
| Bradford | 1.1 | 0.4 | 0.9 | 1.7 | 1.4 | 0.4 | 0.8 | 0.5 |  |
| Bristol | 1.3 | 1.9 | 1.0 | 0.5 | 0.5 | 0.6 | 1.3 | 1.2 |  |
| Cardiff | 1.7 | 2.1 | 1.0 | 0.0 | 0.8 | 3.7 | 1.6 | 1.5 |  |
| Leeds | 0.9 | 0.3 | 1.8 | 1.1 | 1.9 | 0.8 | 1.2 | 0.9 |  |
| Leicester | 0.2 | 0.4 | 1.3 | 0.0 | 1.2 | 0.0 | 0.9 | 0.4 |  |
| Liverpool | 1.2 | 1.3 | 1.6 | 0.5 | 1.9 | 0.9 | 1.2 | 0.7 |  |
| Manchester | 1.5 | 2.1 | 1.5 | 1.1 | 1.0 | 1.5 | 1.6 | 1.5 |  |
| Sheffield | 1.2 | 0.8 | 1.1 | 0.8 | 1.1 | 1.6 | 1.3 | 0.6 |  |

When using total miles (calculated from the population) as a method of exposure, we can see that, in 2013, Cardiff had nearly double the rate of female KSI cyclists as the next highest city (Inner London) (table 5). However, on average over the nine years, the highest was Inner London, Cardiff, Manchester and Bristol. The lowest average rates were Leicester, Bradford and Birmingham. For males, the highest average rates were in Inner London and Manchester.

Rates (calculated from the number of people who cycle to work) (table 6), showed very different results. Bradford had the highest female KSI rates for 2013 and the highest average for males and females. Leicester and Bristol had the lowest average rates for males and females, with Inner London slightly higher.

Using this method, females also had a higher average rate of KSI than male cyclists in all ten UK cities. It is also apparent that the rate per million miles cycled are higher, when using this method rather than population numbers to calculate total miles.

Table 6: Rate of male/female cyclists KSI per 1,000 000 total male/female miles cycled annually (using no. of people who cycle to work for calculation)

| City/area | Rate, year and gender (M/F) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2005 |  | 2012 |  | 2013 |  | All years average |  |  |
|  | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) | $\mathbf{M}$ (rate) | $\mathbf{F}$ (rate) |  |
| Outer London | 23.2 | 54.1 | 27.8 | 50.6 | 18.7 | 30.5 | 23.0 | 49.5 |  |
| Inner London | 34.7 | 85.4 | 36.7 | 69.2 | 21.9 | 59.7 | 31.0 | 73.3 |  |
| Greater London | 29.8 | 74.8 | 33.4 | 63.7 | 20.7 | 51.2 | 27.8 | 65.8 |  |
| Birmingham | 90.0 | 138.1 | 73.0 | 134.7 | 47.5 | 200.6 | 80.3 | 152.0 |  |
| Bradford | 116.2 | 389.0 | 101.7 | 1382.1 | 153.5 | 340.5 | 100.1 | 392.8 |  |
| Bristol | 21.5 | 88.8 | 12.9 | 13.4 | 6.5 | 16.0 | 18.6 | 43.6 |  |
| Cardiff | 54.6 | 210.9 | 27.0 | 0.0 | 21.9 | 255.2 | 39.2 | 120.4 |  |
| Leeds | 53.0 | 84.8 | 86.3 | 244.7 | 87.4 | 176.9 | 69.5 | 215.7 |  |
| Leicester | 5.1 | 36.5 | 35.9 | 0.0 | 33.2 | 0.0 | 29.2 | 40.4 |  |
| Liverpool | 64.5 | 384.4 | 78.3 | 107.4 | 86.4 | 194.7 | 67.4 | 183.7 |  |
| Manchester | 51.6 | 208.0 | 43.8 | 84.1 | 28.6 | 106.4 | 47.9 | 124.8 |  |
| Sheffield | 81.3 | 253.4 | 55.5 | 160.8 | 53.0 | 306.6 | 70.2 | 154.9 |  |

### 5.4 Comparison of the adjusted rates of male and female cyclists KSI in ten UK cities, between 2005 and 2013

The Wald test (assuming a Poisson distribution for cyclists KSI) was used to test the relationship between number of cyclists KSI and gender, using all four exposure measures and whilst adjusting for city and year (appendix 21).

When using population as an exposure measure, comparing female with male cyclists, there is very strong evidence that the relative risk of being KSI decreases by $75 \%$ (RR 0.25, $95 \%$ ( $p<0.001, \mathrm{Cl} 0.23-0.27$ ), when city and area are held constant.

When using the number of people who cycle to work as an exposure measure, comparing female with male cyclists, there is very strong evidence that the relative risk of being KSI decreases by $36 \%$ (RR $0.64, \mathrm{p}<0.001, \mathrm{CI} 0.59-0.69$ ), when year and city are held constant.

When using total miles (calculated using population), comparing female with male cyclists, there is suggestive evidence that the relative risk of being KSI decreases by 7\% (RR 0.93, $\mathrm{p}=0.078, \mathrm{Cl} 0.87-1.01$ ), when year and city are held constant.

When using total miles (calculated using no. of people who cycle to work), comparing female with male cyclists, there is very strong evidence that the relative risk of being KSI increases by a factor of 2.2 (RR $2.16, \mathrm{p}<0.001, \mathrm{Cl} 2.00-2.33$ ), when year and city are held constant.

## 6. DISCUSSION

### 6.1 Principle findings

## 6.1i Numbers of people cycling to work

This project highlights that, nationally, about $1.6 \%$ of women cycle to work, less than half the proportion of males, with this proportion unchanged since 2001. The ratio of male to female cyclists is also unchanged at $73 \%$ : $27 \%$. However this static picture belies the large geographical variation shown in this report. Bristol and Inner London have seen substantial growth in both male and female cyclists but the majority of other cities had much lower rates. In Bradford, $0.5 \%$ of women who travelled to work cycled in 2011 and in Leicester there were decreases in both males and females cycling. This widespread variation suggests that aspects of the cities themselves, perhaps such as policy, infrastructure or the perceived acceptability of cycling, may be affecting the number of women cycling. Generally, those cities where cycling uptake was higher for men also had higher female uptake.

## 6.1ii Numbers of cyclists KSI

In this project, I have demonstrated evidence of geographical variation in KSI numbers. The majority of those KSI in the ten cities, for males and females, were between the ages of 1665 years. In London, working age KSI cyclist numbers have generally increased between 2005 and 2012, although for both genders, there were lower levels in 2013. It is unclear at this stage if this is an anomaly or the start of a downward trend. Generally in London, there were at least double the numbers of male cyclists KSI than females and $21.8 \%$ of all KSI cyclists were women. However the ratio was lower for fatalities and there was a greater proportion of females killed in Inner rather than Outer London.

There was wide variation in the number of cyclists KSI, for both genders, in city comparisons. The numbers of cyclists KSI in Inner London were far higher than the other cities for both females and males. Bristol and Leeds were next highest respectively; Cardiff, Leicester and Bradford had low levels for both. Results also suggested that those areas where KSI numbers were higher for men were also higher for women. For all cities, there were more males than females KSI, however the ratio of males to females was less in Bristol and Inner London than the other cities. The numbers of women KSI were too few to ascertain whether there was a trend in numbers in the nine comparison cities.

## 6.1iii Rates of cyclists KSI

Together, these results demonstrate that cycling uptake and KSI numbers vary by geography and gender. It seems intuitive that this might happen because exposure varies in these cities and any apparent difference in gender may be because of differences in this. However, a very different answer emerged as to why this is, depending on the method of exposure used. Using population alone, Inner London and Bristol had highest rates for males and females, and Birmingham, Bradford and Leicester had the lowest; using number of people who cycle to work, Bradford was highest, with Leicester and Cardiff lowest; using average miles and population, Inner London, Cardiff and Manchester had highest average rates with Leicester, Bradford and Birmingham lowest; whilst, using average miles and those who cycle to work, Bradford had highest female rates with Leicester, Bristol and Inner London lowest.

There was also statistically strong evidence that changing the exposure measure alters the effect of gender on KSI rate, when area and year are held constant. When population is used as a measure of exposure, comparing females to males, there is very strong evidence that the rate of being KSI decreases by $75 \%$. However, when comparing females to males, the rate ratios increased with different exposure methods and the relative risk actually increased when total miles, using average miles and number of people who cycle to work, was used. Thus changing from one exposure method to another can alter both the direction and magnitude of risk and completely alter conclusions on whether females are more at risk than males.

Whilst there is an already strong body of opinion that the use of population data as an exposure method for cycling is flawed (43), I believe that it is likely that the use of population based data will also have a differential bias on female cyclists as, relative to their frequency in the population, they cycle less than males. This makes the use of population data even more concerning. Using an estimate of numbers of cyclists is potentially more accurate though it gives no indication of total exposure (44) and data only exists at regional level and for those who cycle to work. Exposure measures that incorporate distance travelled are most accurate (43) and the NTS uses average distance cycled and population to calculate rates ${ }^{12}$. In this project I have also used a modified version of this approach using number of people who cycle to work. I believe that this latter technique is theoretically most accurate as it encompasses both the number of people cycling and how much cycling they do. However,

[^6]this result is based on survey data, estimation of missing data and the assumption that the majority of people of working age that are commuter cycling are going to work, which is likely to be an overestimate. It is possible that exposure measures based on 'cycling to work' may even be differentially biased when comparing genders because females are known to commute less than males (26). Thus, whilst I believe that the result that relative risk increases by 2.2 when comparing female to male cyclists is likely to be an overestimate, the rate ratio based on population alone is likely to be an underestimate. The current best estimate for rate ratio between the genders is therefore likely to be closer to that calculated using total miles (population and average miles) as an exposure measure and therefore suggests that women have a slightly lower relative risk than men, when area and year are held constant.

### 6.2 Strengths and limitations

## 6.2.i Scope of research

One significant limitation of this project is in my attempt to assess commuter cycling only, and the use of 'cycling to work' as a proxy measure of this, because as many as a third of the cyclists involved in fatal collisions may have been riding 'for leisure or exercise' (38). Yet there is some evidence to suggest that 'commute modal share generally provides a reasonable proxy for total modal share' (45). I have also focussed on working age cyclists to reflect public health aims to increase 'active travel' levels and because one of the only exposure data sets available refers to number of people who cycle to work. I also felt this was most appropriate as collisions involving children and the very elderly might represent different risks, such as from inadequate parental supervision, that do not reflect more general road safety risks.

Another potential limitation of this project regards the cities I chose to study. They represent the most densely populated cities in the UK and a spread of cities across England and Wales. These cities were limited to the DLA that represents the inner city so I compared them to Inner London to represent the same type of urban environment, rather than Greater London, in which there are many suburban Boroughs. By comparing nine cities, I have increased the generalizability of results to UK cities as a whole, but my restriction to large cities has reduced the validity of results for rural areas and smaller cities, several of which are known to be 'cycling friendly' and even 'Cycling Demonstration cities' (46). This project's size constraints have also limited my ability to make a deeper comparison with international cities, as had originally been planned. I believe that to do so would have reduced the depth
of analysis and understanding about women cycling in UK cities that has been gained by this more limited focus.

## 6.2.ii Data limitations

One of this project's greatest strengths is its use of multiple exposure sources to explore KSI rates. To my knowledge, it is unique in this attempt and therefore offers an important insight into how these measures affect rates. However, my use of routinely collected data sources has reduced the reliability of results.

STATS19, for example, was designed to record motor vehicle collisions and has well documented limitations when used for collisions involving cyclists (43)(47), because of underreporting (48)(49) and misclassification of injuries by police officers (44). Although my comparison of cyclists to other cyclists is likely to have reduced the effect of reporting bias, it is possible that KSI rates may have been underestimated.

National Travel Survey data are also limited by small sample sizes, leading to a requirement to collate results by regions and over two years. These limitations can reduce accuracy, reflected in the fact that the NRTS (National Road Traffic Survey) and the NTS show 'different annual totals and trends' (17). However, the NRTS, another often used source of pedal cycle exposure data, does not collect any cyclist specific information, so NTS remains the only available source for exposure by gender.

The Census' large sample size and robust methodology (45) allows us to understand overall changes and trends but questions such as 'method of travel to work' may be prone to reporter bias, as cycling may be seen as a 'correct', healthy answer. However, again, it seems unlikely that these problems should affect one gender and one geographical area differentially. Further data from TfL traffic counts would have aided this research but, unfortunately, there was no response from general or individual contacts at TfL within the time frame of this project.

## 6.2.iii Statistical analyses

Statistical analyses in this project have helped me to quantify the weight of evidence for differences seen in results. However I have made assumptions during these analyses, such as that area and year might confound gender in Poisson calculations, and not further assessed for other potential confounders. Estimations were also made for numbers of cyclists, between the 2001 and 2011 Census and for 2013 NTS results, and I made an assumption that change in numbers would be uniform across time. Whilst this and the small
sample sizes in cities are likely to have reduced the internal validity of results, lack of available data limited the options to deal differently with these problems. However, perhaps one of the greatest weaknesses of this project was the use of regional data to represent individual city results. This represents a large assumption as, particularly in regions that contain more rural areas, such as Wales and the South West, this may not be accurate and it is possible that this may affect female data differentially, as women commute less.

### 6.3 Results in the context of the literature

The rates of cycling seen in this project suggest that public health policies to increase cycling have had little impact and cycling levels in England and Wales remain 'at the low end', alongside other countries such as Australia, the USA and Ireland (50). This result is in keeping with previous literature, reviewed above, that demonstrated a high female to male ratio of cyclists in UK cities (23). It is also clear that the rate of female cycling nationally, and across all our city comparisons, remains lower than international comparators such as the Netherlands (31); this is in contrast to walking, which does not show the same geographical variation (28).

Why this difference remains is unclear but it is likely that it reflects the more longstanding pro-cycling transport policies that cities with a high modal share of cycling have (50). This project also supports the idea that policy can affect cycling, as cycling uptake was highest in two cities that have invested heavily in cycling, Bristol and London. London has a strong policy aim to increase cycling and plans to spend a further £913 million on cycling over ten years (51) and Bristol too has invested heavily ( $£ 23$ million) in cycling since it was named England's first and only 'Cycling City', in 2008 (52). It therefore seems unsurprising that this higher investment, policy and planning should have led to greater cycling uptake than in other cities. However it is also interesting to note that, in cities with large investment in cycling, there also appears to be less difference in the proportion of males and females cycling, which is in keeping with previously discussed findings (7). My results also agree with the previous literature that the proportion of males to females KSI varies geographically, with females making up a higher percentage of the total KSI cyclists in cities with higher cycling uptake (Inner London and Bristol) (38).

Previously published figures for injury rates suggest that the UK has a three times higher rate of cyclists injured than the Netherlands, with 5.7 cyclists injured per 10 million Km cycled in the former and 1.6 in the latter, but less than other comparable countries such as
the USA, at a rate of 33.5 (50). Whilst these figures are not directly comparable to ours, due to use of different injury definitions, age bands and exposure measures, average rates for cities in this project appear higher and fall between these quoted UK and USA rates. Interestingly, results in this project using the exposure measure of total miles (calculated using population), which is commonly used in comparisons, suggest that some cities with a higher percentage of people cycling to work, such as London, have higher KSI rates. Yet this is not in keeping with the 'Safety in Numbers' hypothesis that states that, for any one area, cycling risk decreases as cycling numbers increase, due to more awareness, lower car use and greater political will (53). This suggests that either this hypothesis may not apply to some UK city data, that cities such as London have a worryingly high KSI risk, that the 'safety in numbers' threshold has not yet been reached in these cities, or that using number of people cycling to work as an indicator of cycling levels is not as accurate as supposed.

There were no directly comparable international city rates for female KSI cyclists that were available after literature searching for this project. This may reflect the fact that few countries have as robust a survey system as the UK's Census and NTS and that there is no internationally agreed measure of exposure. Indeed many official bodies continue to quote population as a rate denominator. In one recent publication, for example, the Netherlands is reported to have the highest proportion of cycle fatalities (41\%) in the EU (54), illustrating the fact that exposure measurement is particularly problematic for countries with high female cycling uptake, such as the Netherlands (55).

### 6.4 Implications for future research

A more detailed further analysis on the demographics of cyclists in England and Wales could add much to our understanding of how to increase cycling uptake. For example, we do not currently have information on numbers of cyclists by ethnic background or by deprivation, other than from Cycle Scheme data, and it is therefore hard to assess how significant some of the barriers to female cycling may actually be.

Our understanding of these results would also be deepened by further research into how collisions analysed in this project occurred. Evidence suggests that there may be geographical variation in the type of accident that a cyclist has, with collisions involving HGVs proportionally more frequent in London and females making up a greater proportion of cyclists killed in them (38). Further analysis of STATS19 data in these comparison cities
would help clarify if this type of collision is indeed of particular concern for females in London and whether other factors, such as time of day and weather conditions, might be important.

An extended comparison of this data with primary rather than secondary international data sources would also add insight into how female cycling in the UK compares internationally. However, unless the calls to standardise exposure methods are answered, this kind of research continues to be hampered by methodological difficulties.

### 6.5 Implications for public health policy

This project adds weight to the need for public health to continue to encourage policy, investment and infrastructure changes to increase cycling. The recent transfer of public health from the NHS to local government may offer an opportunity to take a local approach to this. This is supported by my findings that uptake varies geographically, which may be an effect of different funding and policies for cycling. There has also been a plateauing of cycling uptake in some cities and these DLAs need to make particular efforts to increase cycling. Whilst there is also a particular need to increase the number of women cycling, this project supports evidence that the proportion of females cycling increases as the proportion of all cyclists does (7); this suggests that public health should continue to attempt to increase cycling uptake generally, rather than specifically targeting women.

This project has confirmed that cyclist safety is still a perceived and real problem; between 2005 and 2013, in Greater London alone there were 4301 cyclists KSI, 933 of whom were women. Though these numbers remain relatively small compared to other public health priorities, cycling-related injuries are avoidable and international evidence suggests that they can be lower. Research from London also suggests that women may be at greater risk of certain types of cycling accidents and this needs further investigation and potentially targeted campaigns if found to be the case. If nothing else, reductions in KSI numbers would serve to reassure cyclists that the overall risk from cycling is low, thereby further encouraging women to cycle.

The finding that KSI rates can significantly vary depending on the exposure method used is of great public health importance because it suggests that previously published rates, which use population as a denominator, may not be accurate. In 2009 the Department of Transport recognised the need to include exposure data in assessment of cycling risk (46) and this report adds weight to the call to work towards a reliable and uniform method of measuring cyclist exposure (53). Until methods for accurately measuring cyclist numbers by gender
become available, I believe that, at the very least, rates should be based on population and average number of miles cycled. Whilst the current economic climate makes it harder to justify further investment in monitoring cycling safety, this project strongly supports the continued existence and expansion of the NTS and suggests that relatively lower-cost mechanisms, such as extending the NRTS traffic counts to include information on gender, might be helpful.

## 7. CONCLUSIONS

Cycling forms a major part of a wider public health drive to increase 'active travel' and evidence has confirmed that women experience health benefits at least as great as men from cycling. Yet cycling remains 'gendered' (35) and women, in particular, cite road safety as a significant barrier to cycling; thus any gender difference in injury risk, whether real or perceived, could have an effect on cycling uptake for women.

In this project I have demonstrated that, in keeping with previous evidence, the proportion of women cycling remains very low nationally but is increasing in cities such as Inner London and Bristol. However, even there, female cyclists represent a small percentage of total cyclists compared with neighbouring countries, such as the Netherlands, where male and female cycling rates are similar. My results have also confirmed that, in keeping with other studies, numbers of men KSI are greater than women and this difference is less in cities where female cycling uptake is higher.

However, perhaps the most significant outcome of this project is what it has taught us about the use of different exposure methods for calculation of KSI rates. All four methods used have inherent accuracy and reliability limitations, which affect their use as exposure denominators. Results from the currently most recognised and reliable exposure measure, population and average miles cycled, suggest that women have a slightly lower relative risk than men but that conclusion alters when other exposure measures are used; thus fears that women are more likely to be injured cannot currently be completely dismissed. I believe this project adds strong weight to the argument that there needs to be a more accurate and uniform measure of exposure to assess cycling risk. Indeed it demonstrates that this problem is actually accentuated when comparing KSI rates across genders and that, without a more reliable and widely accepted method, it is potentially dangerous to make policy recommendations based on KSI numbers or rates based on population exposure alone.

After years of increased investment and policy to support cycling, a change in Government and an altered economic climate have dramatically affected the environment within which public health bodies must now seek to increase cycling uptake and to continue to explore cycling safety. Yet this project adds weight to evidence that pro-cycling investment can potentially make a difference at individual city level. Fortunately, cycling is well supported by enthusiastic individuals and strong voluntary groups and, together with Public Health England, they must continue to put pressure on local government to maintain investment, improve cycling infrastructure and continue to monitor cycling safety. This project suggests
that investment to increase cycling uptake is likely to have a positive impact on men and women and attempts to further encourage female cycling in the UK should continue to focus on the population as a whole.

## 8. RECOMMENDATIONS

This project recommends that

1. bodies such as the Department of Transport, Public Health England, accident prevention and cycling societies need to urgently work together to develop a nationally agreed and recognised exposure method that allows assessment cycling risk by cyclist gender.
2. cycling rates should use an exposure method based on total miles cycled, to include an estimate of average miles and numbers of cyclists, through an expanded NTS, or by expanding the NRTS to include a measure of gender as part of cyclist counts.
3. further analysis needs to be undertaken to understand whether females are more likely to be involved in certain types of collisions, such as those involving HGVs, throughout the UK, in order to update previous analyses suggesting that they are.
4. Public Health England needs to play a more active role in highlighting the cities where cycling uptake is worse and those where rates of KSI cyclists per exposure are higher, thereby helping DLAs to learn from cities with better records of cycling uptake and safety.

## 10. APPENDICES

All appendices are given to the nearest whole numbers for population and numbers of cyclists, one decimal place for ratios, two decimal places for means, standard errors, confidence intervals, rates and percentages, and three decimal places for probabilities.

Appendix 1: Mode of travel to work for England and Wales ${ }^{13}$

| Year of <br> Census | Number responding to <br> question | Male <br> respondents | Female <br> respondents | Number travelling by <br> bicycle | Males travelling by <br> bicycle | Females travelling by <br> bicycle |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2001 | 23627754 | 12791618 | 10836136 | 650977 | 476010 | 174967 |
| 2011 |  |  |  |  |  |  |

13 Table derived from DC7101EWla - Method of travel to work (2001 specification) by sex by age for all usual residents aged 16 and over in employment the week before the census, and 2001 Census Standard Table S1119 for all people aged 16 to 74 working in the week before the Census.

## Appendix 2: Age bands of KSI cyclists in Greater London, by year and gender

${ }^{19}$ For NTS data, working age is 16-64 years.
${ }^{20}$ NTS data is based on regional totals therefore London represents Greater London.

Appendix 19: Total number of miles cycled per person per year (for working age cyclists), in ten cities ${ }^{21}$

19a: using mid-year population estimates multiplied by average miles (to nearest whole mile)
